Genetic evidence for the primary candidate set

The main analysis uses CI-derived MVP SE; source P/CI convention remains unconfirmed.

a

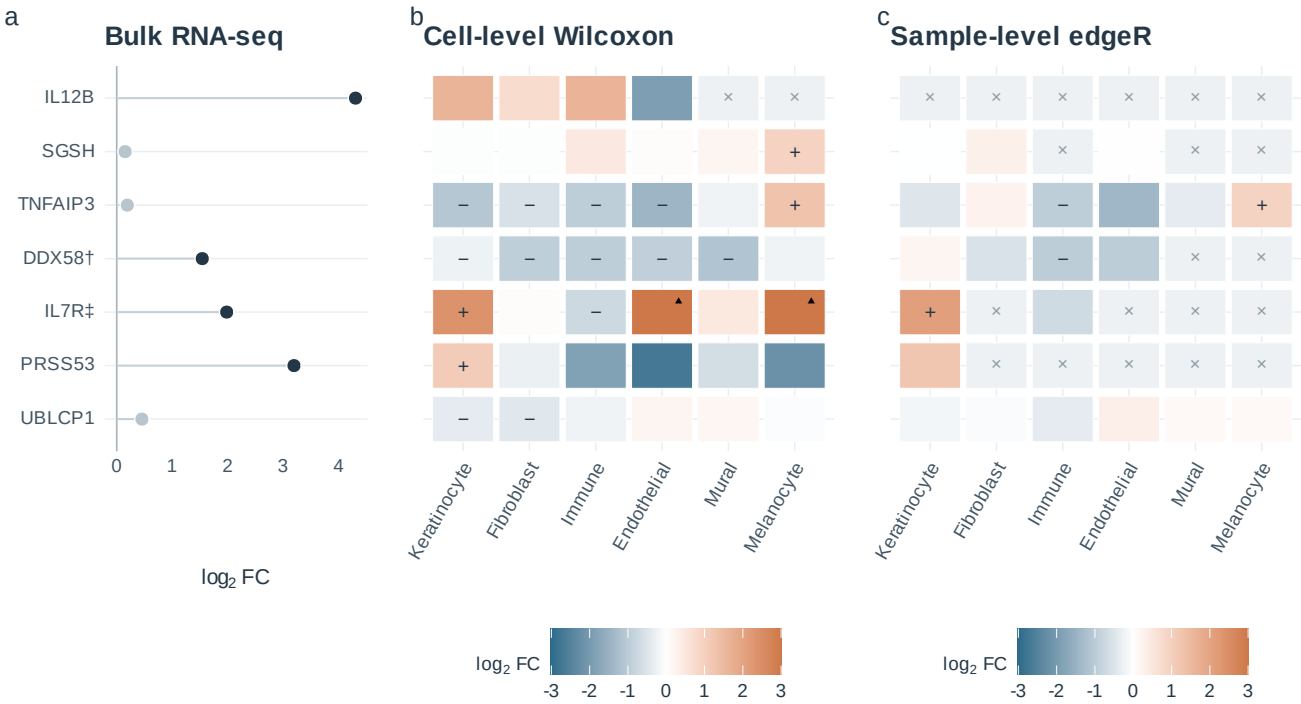

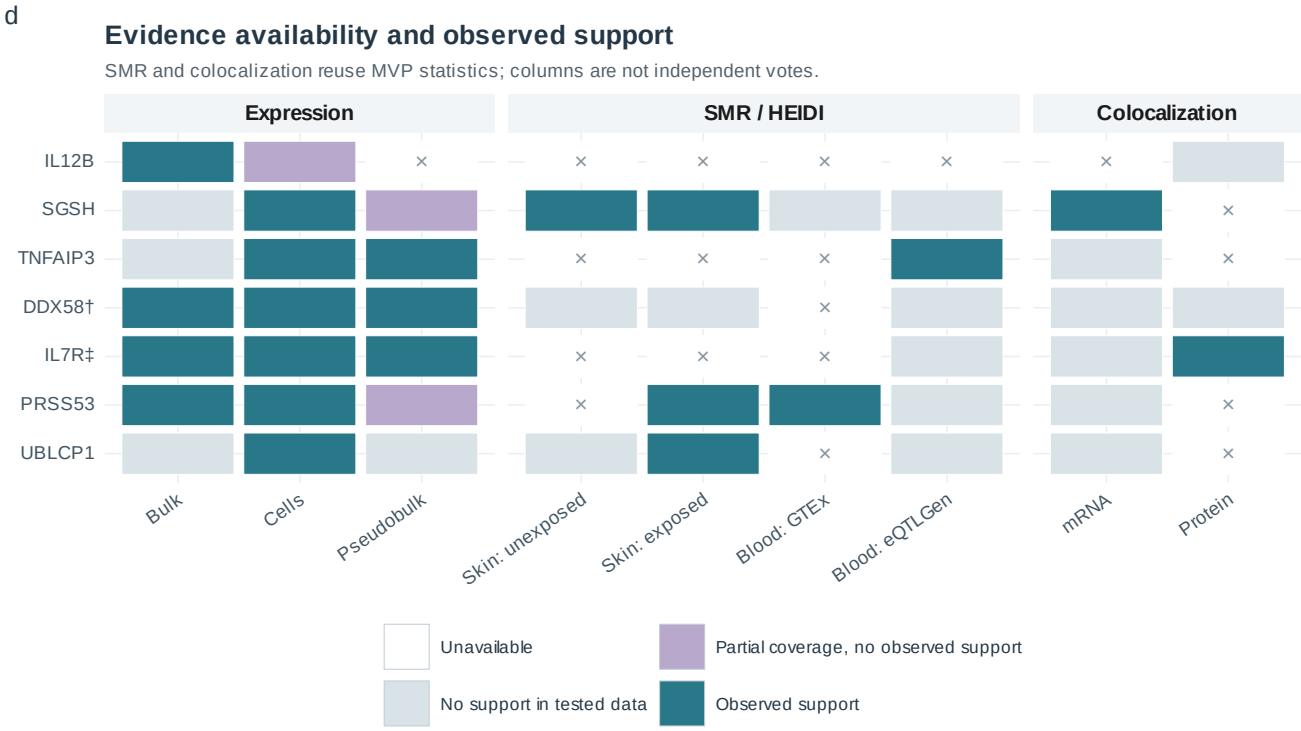

b

Expression and genetic-context evidence

Original whole-study testing families are retained; missing comparisons are never filled with zero.

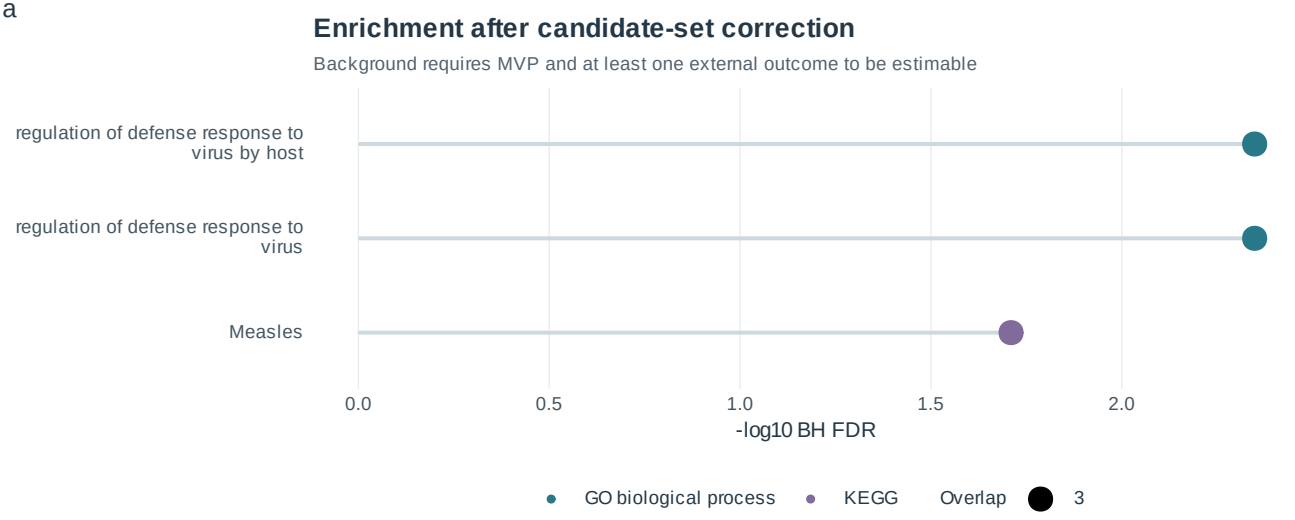

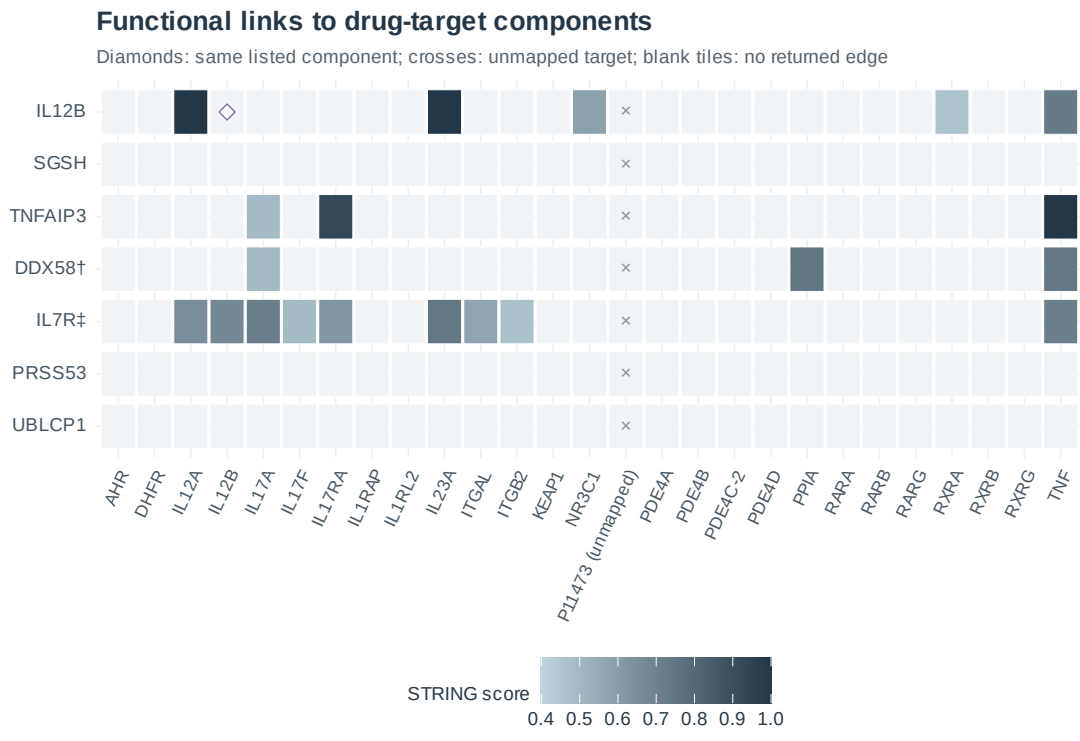

Functional context of the primary candidates

No direct single-protein drug-target record is present in the archived snapshot.

a

b

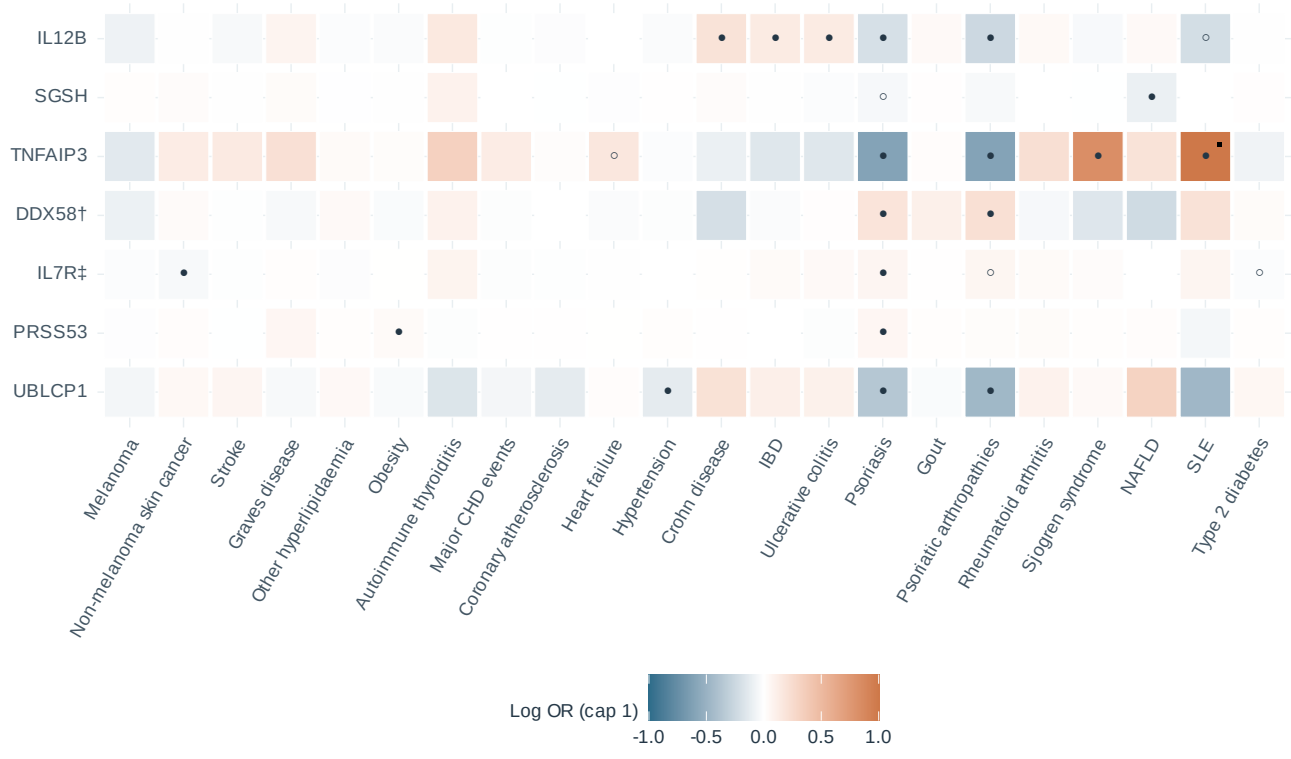

Clinical context and dependence on MVP

The role-reversed control is post hoc; associated proteins may share the same genetic variant.

a

Exploratory clinical associations

Filled: BH<0.05 in the earlier 374-test family. Open: only in the post hoc 154-test family.

b

Control without MVP statistics

FinnGen discovery; Stuart nominal same-direction support; existing datasets with roles reversed
